

Matrix Representations of Abelian Automaton Groups

Tim Becker & Klaus Sutner

Abstract

Representing groups concretely may aid in solving group-theoretic computational problems, and some representations will provide more insight than others. In this poster, we give an efficient algorithm to compute a linear-algebraic representation of abelian automaton groups, along with a basis of identities that hold in the transduction group.

Automaton Groups

A *binary invertible transducer* is a Mealy machine of the form shown below.

For each state q we have length-preserving transduction \underline{q} . These transductions (along with their inverses) form a group under composition, denoted $\mathcal{G}(\mathcal{A})$. A transduction $f \in \mathcal{G}(\mathcal{A})$ is called *odd* if it flips the first bit of its input; otherwise f is called *even*. We also have the *residuation* maps $\partial_a : \mathcal{G}(\mathcal{A}) \rightarrow \mathcal{G}(\mathcal{A})$ for $a \in \{0, 1\}$. In the example above, $\partial_0 \underline{0} = \underline{1}$ and $\partial_1 \underline{0} = \underline{2}$.

Let \mathcal{A} be a transducer with n states $\{s_1, \dots, s_n\}$ whose transduction group is abelian.

Proposition 1. *There is an epimorphism $\psi : \mathbb{Z}^n \rightarrow \mathcal{G}(\mathcal{A})$ given by $\psi(a_1, \dots, a_n) = \underline{s_1}^{a_1} \dots \underline{s_n}^{a_n}$*

Proposition 2. *Define the 1/2-transition matrix as follows:*

$$B_{i,j} = \begin{cases} 1 & \text{if } \partial_0 \underline{s_i} = \partial_1 \underline{s_j} \\ \frac{1}{2} & \text{if } s_i \text{ is a toggle state and } \partial_0 \underline{s_i} = \underline{s_j} \text{ or } \partial_1 \underline{s_i} = \underline{s_j} \\ 0 & \text{otherwise} \end{cases}$$

Then B performs residuation on even states. That is, for any $v \in \mathbb{Z}^m$ such that $\psi(v)$ is even, $\partial_a \psi(v) = \psi(Bv)$.

Matrix Representations

In [1], Nekrashevych and Sidki proved the following:

Theorem 1. *If $\mathcal{G}(\mathcal{A}) \cong \mathbb{Z}^m$, then there exists an isomorphism $\phi : \mathcal{G}(\mathcal{A}) \rightarrow \mathbb{Z}^m$, an $m \times m$ matrix A , and a vector r which satisfy*

$$\phi(\partial_a \underline{p}) = \begin{cases} A \cdot \phi(\underline{p}) & \text{if } \underline{p} \text{ is even} \\ A \cdot \phi(\underline{p}) + (-1)^a r & \text{if } \underline{p} \text{ is odd} \end{cases}$$

Also, the matrix A satisfies several interesting properties:

- *A is contracting, i.e., its spectral radius is less than 1.*
- *The characteristic polynomial $\chi_A(x)$ is irreducible over \mathbb{Q} , and has the form $\chi_A(x) = x^m + \frac{1}{2}g(x)$ where $g(x) \in \mathbb{Z}[x]$ is of degree at most $m-1$.*

We call this A and r the *residuation pair* for the automaton \mathcal{A} . We prove some additional properties of A .

Lemma 1. *The map $R = \psi \circ \phi$ is a surjective linear map $\mathbb{Z}^n \rightarrow \mathbb{Z}^m$, and for all $k \geq 1$, $RB^k = A^k R$.*

Proof. ψ is surjective and ϕ is bijective, so R is surjective. Since $\psi \circ B = \partial_a \circ \psi$, we have $RB = AR$. The claim follows by induction. \square

Lemma 2. *The characteristic polynomial of A divides the characteristic polynomial of B .*

Proof. By the previous lemma, for any polynomial P , $RP(B) = P(A)R$. Apply Cayley-Hamilton. \square

Lemma 3. *Let A' be the companion matrix of χ_A . We say A is well-behaved if A is $GL(m, \mathbb{Z})$ -similar to A' , i.e. if there exists an invertible $m \times m$ integral matrix T such that $TAT^{-1} = A'$. If A is well-behaved, then (A', Tr) is a residual pair.*

Proof. For all $v \in \mathbb{Z}^m$ and $c \in \{0, \pm 1\}$,

$$T(Av + cr) = T(T^{-1}A'Tv + cr) = A'(Tv) + cr'$$

An Algorithm

Theorem 2. *There is a polynomial time algorithm to compute a residuation pair A, r for a well-behaved abelian automaton \mathcal{A} .*

Proof. For each irreducible factor f of $\chi_B(x)$ of the form $x^k + \frac{1}{2}g(x)$ where $g(x) \in \mathbb{Z}[x]$ has degree less than k , let C_f be the companion matrix of f . Solve the matrix equation $RB = C_f R$ for R , which can be done using Kronecker Products. Such a solution is guaranteed to exist because C_f and B share eigenvalues. Once R is computed, we can compute r as follows. Let s_a be an odd state in \mathcal{A} and let $s_b = \partial_0 s_a$. Let e_i denote the i th standard basis vector, such that $\psi(e_i) = \underline{s_i}$, and compute $r = Re_b - A'Re_a$. We can now simply check if (C_f, r) is a residuation pair for \mathcal{A} .

By Lemma 2, one of these factors must be χ_A , and since \mathcal{A} is well-behaved, (C_f, r) will be a residuation pair for some factor f . \square

Theorem 3. *The matrix R computed in the above algorithm gives a basis of identities holding in $\mathcal{G}(\mathcal{A})$.*

Proof. Since A' is a contraction, A'^k has no nontrivial fixed points for all $k > 0$. Thus the only identity in $R(\mathbb{Z}^n)$ is $\vec{0}$, and computing the null space of R gives the basis of identities. \square
